Assay Summary

MUTYH Gene Mutation Analysis
MUTYH-Associated Polyposis

Synopsis
MUTYH-associated polyposis (MAP) (OMIM #608456) is an autosomal recessive disorder characterized by multiple colorectal adenomas and carcinomas. Individuals with MAP have an extremely high risk of developing colorectal cancer. MAP is caused by biallelic germline mutations in the mutY homolog (MUTYH) gene.\(^1,2,4\) The mean age of colorectal cancer diagnosis in untreated individuals is 45 years, several years later than in APC-related familial adenomatous polyposis (FAP).\(^9\) The phenotype is often indistinguishable from that of autosomal dominant FAP or attenuated FAP (AFAP) caused by mutations in adenomatous polyposis coli (APC) gene. The number of polyps in MAP patients is usually between 10 and 100, and affected individuals are often sporadic cases. However, biallelic MUTYH mutations have also been detected in patients affected with early-onset colorectal cancer without polyps and in one with more than 1000 polyps.\(^7,8\) The two most common mutations in Caucasians, accounting for about 75%-80% of mutant alleles, are Y165C (or Tyr165Cys) and G382D (or Gly382Asp).\(^5\) Prevalence of MUTYH mutations in other ethnic groups is currently unknown. The exact risk of colorectal cancer associated with monoallelic MUTYH mutation carriers remains uncertain; most large studies have described an odds ratio of <1.5.\(^6\)

MUTYH gene is located on the short arm of chromosome 1 between positions 34.3 and 32.1.\(^3\) MUTYH is frequently also termed MYH. MUTYH is part of the Base Excision System which is responsible for the repair of oxidative DNA damage. Since 2002, biallelic germline mutations in the MUTYH gene were found to result in the accumulation of G:C→T:A transversion mutations in genes such as APC and KRAS, both of which have major roles in colorectal tumorigenesis.\(^1\)

Indications for testing
1) Individuals with FAP-like and AFAP-like phenotypes and in whom no inherited APC mutation could be identified
2) Predictive testing for at-risk family members of an individual diagnosed with polyposis and who tested negative for mutations in APC gene.

Methodology
Full gene sequencing of MUTYH: Coding exons and associated intron junctions are captured and enriched using custom Agilent SureSelect technology. Next-generation sequencing is performed on Illumina MiSeq. Additional Sanger sequencing is performed for any regions with insufficient depth of coverage or for verification of suspect variant calls. Targeted testing for known familial mutation is performed by Sanger sequencing.
**Limitations**

This method will not detect mutations located in regions of the genes that are not analyzed (non-coding exon sequences, intron sequences other than the splice junctions, and upstream and downstream sequences). The method also will not detect inversions. Some sequence alterations that may be detected (such as those causing missense or synonymous changes) will be of unknown clinical significance. Interpretation of test results should be in the context of the patient’s diagnosis, ethnicity, clinical and family histories, and other laboratory test results.

**Specimen Requirements**

Blood samples: 2 tubes with a total of 6 ccs in ACD (yellow top) or EDTA (lavender top) tubes.

Keep at ambient temperature and ship by overnight courier. Samples must be received in our laboratory within 72 hours of draw.

**Note:**
- i) for infants, a minimum of 3 ccs is sufficient.
- ii) we accept DNA; at least 10 micrograms is required.

**Test Request Form (TRF)**

a) A completed CMDL TRF is required for each specimen. Please submit the completed TRF with the specimen. Complete testing and billing information must be provided before the specimen is processed.

b) **General Cancer Patient Information Form**: Include a completed General Cancer Patient Information for the proband and a complete pedigree.
